Abstract

Formative assessments allow learners to quickly identify knowledge gaps. In traditional educational settings, expert instructors can create assessments, but in informal learning environments, it is difficult for novice learners to self assess because they don’t know what they don’t know. This paper introduces Questimator, an automated system that generates multiple-choice assessment questions for any topic contained within Wikipedia. Given a topic, Questimator traverses the Wikipedia graph to find and rank related topics, and uses article text to form questions, answers and distractor options. In a study with 833 participants from Mechanical Turk, we found that participants’ scores on Questimator-generated quizzes correlated well with their scores on existing online quizzes on topics ranging from philosophy to economics. Also Questimator generates questions with comparable discriminatory power as existing online quizzes. Our results suggest Questimator may be useful for assessing learning in topics for which there is no existing quiz.
Acknowledgments

First and foremost, I would like to express my sincere gratitude to my advisor Prof. Emma Brunskill who has introduced me to rigorous research, and been really supportive through the ups and downs during the two years. I am also deeply grateful for my other research mentors, Prof. Jeffrey Bigham, Prof. Niki Kittur and Prof. Chinmay Kulkani, without whom this thesis would not have been possible. You are all great researchers. Your guidance, encouragement and knowledge have been invaluable assets for my research. It was a great pleasure to work with you all.

Further, my sincere thanks go to my amazing labmates and friends, from whom I have learned how to be a better person, not to mention the useful discussions and loads of fun. You know I am talking about you. I wish you all the best in your future endeavor.

I also gratefully acknowledge the assistance and helpful feedback of more than 800 participants from Amazon Mechanical Turk. Thanks for taking a quiz seriously.

I should probably give some credit to the nice view from our lab, which has nice chemistry with the volatile Pittsburgh weather.

My research was supported by a CMU ProSEED/Simon Initiative Seed Grants and a Google focused research award.

Chapter 1

Introduction

An increasing number of learners are opportunistic and self-driven [5, 7, 34]. Online learning opportunities such as MOOCs attract diverse students with a range of prior knowledge and experience [22]. While online resources are a boon to self-directed learning, knowledge gaps cause learners to struggle with new material, lose motivation, and even avoid future subjects due to lowered self-perceived efficacy [17].

Figure 1.1: Questimator automatically produces quizzes of multiple-choice questions to assess knowledge for arbitrary topics contained within Wikipedia. (The selected answers in the figure are correct answers.)
Assessments can help learners diagnose what they know, which may be particularly helpful in informal learning domains, so as to direct their learning in more effective ways. Knowing about their knowledge gap could help them direct their learning to first understand foundational topics before tackling more complex topics. Unfortunately informal learning domains are precisely those that often lack formal assessments. Relying on learners’ self-diagnosis is tricky because they don’t know what they don’t know [8]. Furthermore, learners tend to overestimate the degree of their factual knowledge, leading to over-confidence [11].

Traditionally, formative assessment of factual knowledge has relied on experts, such as teachers or textbook authors. However, what such expert resources provide in quality, they lack in breadth [12]. Because creating formative assessments of factual knowledge is time-consuming, such assessments are limited to a small set of common topics of interest. Furthermore, such assessments are often missing for new or esoteric topics.

How could a self-directed, informal learner assess their knowledge, say, on an arcane but upcoming technology? How could a Star Wars fan gauge their knowledge on the upcoming movie release? Or perhaps more importantly, how could an intelligence analyst track their knowledge of recent geopolitical events?

This paper introduces Questimator (described in Section 3), which, to our knowledge, is the first system that automatically generates multiple-choice question (MCQ) quizzes for general topics from large networked corpora like Wikipedia, thus significantly extending the scope of automatically generated questions. For example, Figure 1.1 shows Questimator’s automatically generated assessment for the topic of “Reinforcement learning”.

A learner uses Questimator by inputting a topic they would like to learn about, e.g. “reinforcement learning” or “France”. To generate a coherent quiz, we need questions covering different perspectives of that topic. Unfortunately, previous work (Section 2) on MCQ generation did not provide a principled approach. We propose a method (contribution 1) to find topics that are related to the input topic (Section 3.1) and generate questions for those related topics. We utilize the Wikipedia page-to-page linkage graph and word embedding to this end.

Multiple-choice question (Section 3.2) contains three components: (i) a question stem, (ii) a correct answer, and (iii) a set of distractors (usually, at least 3). The question stem (Section 3.3) is the part where the item to ask for is stated, for example “Reinforcement learning is ____.” The examinee then chooses from the correct answer and distractors. We propose a novel method (contribution 2) to find distractors (Section 3.4), combining Wikipedia’s categorical structure (treated as a bipartite graph between the set of categorical labels and the set of articles), word embedding and sentence embedding.

In a controlled experiment with 833 participants from Mechanical Turk, we found that participants’ scores on Questimator’s generated quizzes are significantly and positively correlated with their scores on existing online quizzes across a variety of topics, with correlations of similar magnitude to those between existing quizzes. For certain factually-oriented topics (such as customer satisfaction), this correlation was approximately the same as score correlations between two existing online quizzes.

By strengthening related topic search and distractor generation with Wikipedia’s graph structure and semantic embedding, Questimator advances question generation to arbitrary topics. Through Questimator, we demonstrate the feasibility of leveraging existing corpora of knowledge such as Wikipedia to create interactive testing materials.
Figure 1.2: When learners enter a topic, Questimator extracts the wiki links on the page and finds related topics. A question is then generated for both the input topic and each of the related topics. To generate a question from a topic, categories from the Wikipedia page for the topic are used to generate similar topics. Sentences extracted from these pages are then turned into question stems and both correct answers and distractors. In the case of distractors, similarity and tense matching are used to pick the final distractors. The question stem, correct answer, and distractors form the final output question.
Chapter 2

Related Work

2.1 Automatic MCQ Generation

Questimator is most closely related to prior systems for generating textual multiple-choice questions, as creating questions for math or logic involves different techniques. Most prior methods for generating text-based questions start with an input article. The question and correct answer are derived from this article (often from a single sentence). And they mostly aimed at language learning [6, 15, 18, 23, 27, 28, 35] or a single subject/textbook [1, 3, 36].

These prior approaches to generating MCQ quizzes are limited to using a single document or a fixed ontology alone to generate questions and distractors. Generating questions from a single document often scopes questions too narrowly to assess a learner’s understanding of a general topic, which typically spans related documents. Related topic selection is addressed in Section 3.1.

Also, while previous approaches work well for language learning or single subject, they suffer from limited choices of distractors when directly applied to general topics. Some systems pick distractors (having same POS tag as the correct answer) within the same article/textbook, based on term frequency etc. [1, 18]. Using terms from the article as distractors can be problematic, because good distractors might not be frequently mentioned in the article. For example, “Formula Two” is a good distractor for “Formula One”, but does not have a high frequency in the Wikipedia article for “Formula One”. Other systems use fixed ontologies or dictionaries, such as WordNet, to find synonyms or other related words to use as distractors [15, 27]. Although WordNet has 117,000 synsets, it focuses more on a limited type of cognitive concepts, rather than general knowledge concepts. For example, it contains “baby”, and groups it with “infant”, but it does not contain “Baby”, the Justin Bieber hit song. This limitation also applies to other ontologies and dictionaries. In comparison, there are more than 5,129,000 English Wikipedia articles (as of April 2016) for a broad range, including a long tail of esoteric and less well-known topics and contemporary topics.

These approaches have therefore mostly been applied to language (vocabulary) learning and assessment [6, 15, 18, 23, 27, 35], where being able to tell similar words apart is one of the

\[^1\text{WordNet groups nouns, verbs, adjectives and adverbs into sets of cognitive synonyms (synsets). It also encodes hyperonymy (super-subordinate relation).}\]
main tasks for students. A few specific systems have also been developed for domains with domain-specific dictionaries (knowledge bases), like biology [1] and medicine [36].

We use the abundant Wikipedia corpora along with its socially-annotated categorical information [21] to select distractor topics. So Questimator can work across a wide range of domains. In addition, it integrates semantic embeddings when generating distractors.

2.2 Crowdsourcing Question Generation

Crowdsourcing has recently been explored as a way to generate questions. Christoforaki and Ipeirotis [10] ask crowdworkers to directly generate the questions by mining existing Q&A sites. For example, Stack Overflow can be used as a scalable source of coding questions. In fact, a simple web search reveals a number of existing quizzes online for a variety of topics. These are sometimes posted by instructors, textbook writers and even students. Crowdsourcing can be used to help with searching. However this has the disadvantage of extra monetary cost, human selection of topics and additional time delay. Another challenge with these approaches is verifying that the questions are of high quality. Although Wikipedia is crowdsourced, popular articles are quite accurate and complete, and so the questions generated by Questimator are in a sense crowdsourced from source material subject to Wikipedia’s quality control.

Questimator is a new approach to multiple-choice question generation. Inspired by the recent trend to utilize large scale datasets, and enabled by the corresponding development in NLP, Questimator uses a connected set of documents rather than a single document to generate multiple choice questions for general topics.
Chapter 3

Questimator System

Questimator is our system for automatically generating multiple choice questions from Wikipedia. To use Questimator, learners first enter a topic they would like to know about. Questimator matches the entered topic to one that appears in Wikipedia. Questimator then returns a set of multiple choice questions automatically generated from Wikipedia chosen to assess the learner’s knowledge of the provided topic (Figure 1.1 shows the first two questions generated for the topic “Reinforcement learning”). The number of questions to return is configurable (10 by default). To do this, Questimator:

1. generates a list of topics related to the input topic,
2. generates questions for each of the topics by
   (a) generating question stems,
   (b) generating and ranking distractors for each question stem.

3.1 Stage 1: Related topic identification

Related topics for questions can be drawn from prerequisites and subtopics. Given an input (main) topic \(X_0\), to generate candidate related topics \(X_i(i = 1, \ldots, n)\), Questimator leverages both the Wikipedia document for the main topic, and the larger Wikipedia structure to generate and rank related topics.

To rank a candidate related topic \(T\), Questimator uses three measures of similarity:

- Term frequency of \(T\) in the article of \(X_0\)
- backlink overlap between \(T\) and \(X_0\)
- embedded semantic similarity between \(T\) and \(X_0\)

We will elaborate on each of the three features in the following. Questimator combines these measures to produce a single relatedness metric. Questimator then ranks topics based on that metric, and chooses the top \(n \geq 9\) items as related topics to generate questions for the quiz.
3.1.1 Wikilink term frequency

Important concepts are likely to be repeatedly mentioned in the main article of $X_0$, and so term frequency can be an important feature for identifying important subtopics. We extract all the links to other Wikipedia topics in the main article (called pagelinks or wikilinks), and count the term frequencies ($\text{TF}_{X_0}(T)$) of the wikilinks. We take simple coreferences into account, like abbreviations used in the article etc. For example, “MDP” for “Markov Decision Process” given the text “Markov Decision Process (MDP)”, and “behaviorist psychology” for “Behaviorism” given it links to “Behaviorism” in the main article.

The term frequencies alone do not always identify good related topics. For example, “action” is mentioned many times in the article for “Reinforcement learning”, but it is not an important related concept. Neither is “(real) number” for “Invertible matrix”. Related topics are also not comprehensively included in the article, for example, ”Convex Optimization” for ”SVM”.

3.1.2 Backlink Overlap

The topics that co-occur with the main topic frequently are likely to be related. Similar backlinks, i.e. articles which link the topic, may imply topic relation. We find the backlinks of the candidate topics and the main topic, and compute the cosine similarity between their “bag-of-backlinks” vectors using the following formula:

\[
\text{sim}_{bl}(T, X_0) = \frac{\text{backlinks}(T) \cdot \text{backlinks}(X_0)}{\|\text{backlinks}(T)\|_2 \cdot \|\text{backlinks}(X_0)\|_2} = \frac{|\text{backlinks}(T) \cap \text{backlinks}(X_0)|}{\|\text{backlinks}(T)\|_2 \cdot \|\text{backlinks}(X_0)\|_2}
\]

\[\text{(3.1) (3.2)}\]

where $|\cdot|$ is the cardinality of the set, $X_0$ is the main topic, $T$ is any candidate topic. Note here we are representing the backlinks($T$) as “bag-of-backlinks” (in analogy to “bag-of-words”) vectors. So cosine similarity is the typical metric to use.\[1\]

This allows us to identify topics that are overlooked in the main article that can not be identified by term frequency. For example, “Convolutional neural network” for “Deep learning”, and “Affine transformation” for “Rigid transformation”.

As one of the implementation details, we use the pagelink dataset dumped from Wikipedia, instead extracting the linkage information from the article database at the run time. This database contains only information about which topic links to which. It is specifically used for fast backlink queries.

3.1.3 Embedded semantic similarity of topics

We used a Word2Vec \[25\] model trained on Wikipedia articles with topics (article titles) treated as independent entities. Word2Vec provides vector representations for words and can be easily generalized to preidentified noun phrases and other entities in text. Semantically similar words

\[1\] Jaccard index is also reasonable if we simply consider them as two sets.
and entities are mapped to similar vectors. We then measure the similarity between topics $T$ and $X_0$ by their vectors’ cosine similarity,

$$\text{sim}_{\text{word2vec}}(T, X_0) = \frac{\text{vec}(T) \cdot \text{vec}(X_0)}{\|\text{vec}(T)\|_2 \cdot \|\text{vec}(X_0)\|_2}$$  \hspace{1cm} (3.3)$$

Due to various reasons, the Word2Vec model may not have an entity vector for every article title. For example, the dumped Wikipedia articles the Word2Vec was trained on is out-of-date, terms may be changed or missing. In this case, we will treat the title of the wikilink as a list of words, and retrieve from the model a vector for each of the word, and average the word vectors to get a vector for the title.

Adding this feature to the relatedness measure, we might pick out “Backpropagation” for “Artificial neural network”, which does not have either high term frequency or backlink overlap, but is semantically related, as an important optimization method for neural networks.

3.1.4 Combine and Rank Relatedness

We combine the above three quantities, to produce a single scalar used for ranking. We normalize each of the three features independently by $f = \frac{f - \text{mean}(f)}{\sqrt{\text{var}(f)}}$. Then they are truncated to $[-1, 1]$, so a single feature would not play a too significant role in some edge cases. We sum the three features to create a combined relatedness measure,

$$R_{X_0}(T) = \tilde{\text{TF}}_{X_0}(T) + \tilde{\text{sim}}_{\text{bl}}(T, X_0) + \tilde{\text{sim}}_{\text{word2vec}}(T, X_0)$$

These features can be assigned different weights, here we simply set them to be equally weighted. Links are finally sorted by their relatedness values, and the top $n$ are picked as related topics to generate questions. For example, the related topics picked for “Reinforcement learning” are “Markov decision processes”, “Software agent”, “Dynamic programming”, “Temporal difference learning”, “Supervised learning”, “Machine learning”, “Optimal control theory”, “Gradient descent” and “Q-learning”.

3.2 Stage 2: Single question generation

Recall that a multiple choice question (MCQ) is composed of a question stem, a single correct answer and a set of distractors. Given a topic $X_i (i = 0, \ldots, n)$ as input, Questimator generates a single MCQ as following:

- Question stem and correct answer are generated first from the same sentence,
- distractors are generated separately from articles of similar topics.

We elaborate on the above two phases of the pipeline separately in the following section.

3.3 Stage 2(a): Question stem generation

Questimator generates questions directly testing on concept explanation are frequently used in expert assessments, by asking about the verbal phrases after the topic noun phrases in the main
clause. Questimator generates *gap-fill questions*, as the stems, avoiding the need to transform sentences to interrogative form. To generate a question stem for a given topic, Questimator retrieves the Wikipedia article of the topic, and

- finds a set of sentences that each contain the stemmed tokens of the topic string, and process them by their order in the article,
- parses a sentence into a PCFG syntax tree, and match the syntax tree with certain syntactic phrase patterns [33],
- if matched, substitutes the matched phrase with a blank to generate the question stem, and uses the matched phrase as the correct answer.

Then Questimator processes the sentences by their order in the article, as the first few sentences where the main topic is mentioned usually contain an explanation of that topic. Note the second step is similar to Heilman and Smith [16].

Additional types of question stem can be generated by simply inserting more TGrep patterns into Questimator. As a byproduct of limiting the question stem types, we avoid the problem of choosing the proper question type.

### 3.4 Stage 2(b): Distractor Generation

Different from previous approaches, we propose to generate distractors utilizing the Wikipedia categorical information, and word/sentence embedding methods. To generate distractors, Questimator

- finds topics in the same categories as the main topic,
- ranks them by their Word2Vec semantic similarities with the main topic, and picks the top few topics,
- extracts one distractor phrase for each by matching patterns on syntax tree (same as extracting the correct answer in Section 3.3),
- uses skip-thought vectors [19] to find distractor phrases most similar to the right answer phrase.

Note the finding and ranking of distractor topics is different from question topic selection (section 3.1.1).

#### 3.4.1 Pre-Extraction: Distractor Topic Selection

Unlike searching for related topics as question topics (Section 3.1), the criterion of similarity for selecting distractor topics is different. For example, “Camera Matrix” is a very related topic for “Camera Calibration”, by our former criteria for relatedness. But as a distractor, examinees can easily tell a matrix’s definition from a calibration process. Luckily, semantic information in the definition phrase reveals this difference, so sentence embedding can help. In general, topics at the same level of the category hierarchy are preferred. For example, “Supervised learning” and “Unsupervised learning”, “Formula One” and “Formula Two”. So categorical structure is more informative than linkage graph for this purpose.
Questimator first finds topics sharing at least one category with the question topic to construct a candidate pool. The category information is from Wikipedia’s socially annotated (noisy) category hierarchy. Then Questimator ranks the distractor topic candidates by their Word2Vec similarity (same as in Section 3.1.3) with the question topic, and selects the top ones. For $n_d$ ($n_d = 3$ by default) distractors, Questimator selects $m \cdot n_d$ distractor topics ($m = 3$ by default) to generate the distractor phrases.

### 3.4.2 Category information

Questimator finds categorical information by using Wikipedia’s socially annotated category hierarchy. Although the categorical information is noisy, it can be very useful when combined with other similarity measures.

### 3.4.3 Embedded semantic similarity of topics

The topic semantic similarity measure here is the same as the measure for related topic explained in the former section 3.1.3.

Questimator ranks the distractor topics sharing at least one category with the main topic by their Word2Vec similarity with the main topic, and select the top ones. For $n$ ($n = 3$ by default) distractors, Questimator intermediately select $m \times n$ distractor topics ($m = 3$ by default) to generate the distractor phrases.

### 3.4.4 Post-Extraction: Distractor Phrase Ranking

After we have $mn_d$ distractor phrases, we aim to pick the ones most difficult to distinguish from the correct answers. Questimator applies skip-thought vectors [19] to measure the similarity between the distractors and the correct answer. Like Word2Vec generating vectors for words, skip-thought generates vectors for sentences, with semantically similar sentences having similar vectors. The model is trained on 11,038 novels in 16 genres, and skip-thought used pre-trained Word2Vec models to linearly map words and extend the vocabulary [19].

Questimator throws away phrases containing the stemmed tokens of the main topic string, because there is a high probability that this will reveal itself as a wrong answer. We match the distractors’ tenses with the correct answer. This prevents the examinees from identifying them as wrong answers by tense mismatch. Here the definition of tense is generalized. Instead of only indicating time for the verb, tense here includes (Tense, Person, Number).

### 3.5 Questimator MCQ Example

Finally distractors together with the question stem and the correct answer are delivered as a whole MCQ. The following is an example of a whole MCQ (correct answer in italics):

A recurrent neural network (RNN) is _____.

- a class of artificial neural network where connections between units form a directed cycle
• an artificial neural network where connections between the units do not form a directed cycle
• a parallel computing paradigm similar to neural networks, with the difference that communication is allowed between neighbouring units only
• a type of artificial neural network in which an electrically adjustable resistance material is used to emulate the function of a neural synapse

One of our goals in developing Questimator is for it to generate multiple-choice quizzes at scale for topics that do not already have quizzes available online. We maintain an updated corpus of quizzes generated from the most popular Wikipedia articles at [https://crowdtutor.info](https://crowdtutor.info). For many topics, such as “Wonders of the World” and “Oasis (band)”, no other existing quizzes are readily available. For topics like the ongoing “Syrian Civil War”, expert-generated quizzes, even if available, are likely out-of-date. Finally, for some topics, such as “Fascism” and “Constructivism”, we found that Questimator generated questions similar to those on existing quizzes.
Chapter 4

Evaluation

The goal of Questimator is to generate good MCQ quizzes for knowledge evaluation for arbitrary topics.

To preliminarily evaluate the quality of Questimator questions, we asked 4 TAs to inspect 258 Questimator questions (each question has one labeler), with most of the questions in their areas of expertise. 78% were labeled useful for assessment. Problems with the others included multiple correct answers (36%), irrelevant question topic (22%), obvious answer (21%), all wrong answers (20%) and typos (11%). This kind of labeling has been used in previous work (Section 2). While it gives an idea how effective Questimator is at generating reasonable questions, it does not assess the actual ability of questions to discriminate between different levels of knowledge. For example, while both expert-generated and machine-generated questions might be ambiguous, expert-generated questions might nudge students to think more critically, while machine generated ones might not.

To assess ecological validity, we compared actual student performance on Questimator quizzes to student performance on expert-generated quizzes. Note that experimental comparisons with previous work are too difficult to run due to the lack of shared resources. We focused on two key measures:

1. the correlation between a student’s performance on a set of Questimator-generated questions, and the same student’s performance on a set of human expert generated questions (Section 4.3), and
2. the discriminatory power of individual Questimator-generated questions, in terms of their ability to distinguish between students’ with varying topic knowledge states (Section 4.4).

Our motivation for the first objective is that we would like Questimator to automatically construct a quiz that provides a measure of student knowledge that is similar to an assessment constructed by expert teachers. If Questimator can provide an assessment such that a student’s performance on said assessment correlates highly with the same student’s performance on an expert-constructed assessment, that provides encouraging evidence that Questimator is able to capture signals that provide important insight into a student’s knowledge\footnote{Indeed, correlation alone may be sufficient to create a system that can be used for certification. On the other hand, high correlation between an automatically constructed assessment may be useful, but not sufficient for identifying the important aspects to teach a student. For example, imagine that a student’s ability to define a particular topic}. Therefore, we focus
our evaluation on comparing student performance on quizzes generated by Questimator to those
generated by experts on a diverse set of topics.

The second objective stems from wanting a deeper understanding of the quality of the individ-
ual questions generated by Questimator. We would like to better quantify how effective different
automatically-constructed items are at assessing student knowledge, and how these compare to
expert-generated questions. This could also have interesting implications for future work which
may generate many questions and then subsample the more discriminative ones with different
difficulty levels.

### 4.1 Experimental Setup

Our evaluation was a within-subjects experiment with participants drawn from Amazon Mechanical
Turk. In this setup, each learner sees a quiz on a particular topic that is composed of both
expert and Questimator generated questions.

#### 4.1.1 Choosing topics

We evaluated Questimator on a diverse set of 10 topics. We chose topics for evaluation based on
three criteria. First, because our participants were drawn from Mechanical Turk, we chose topics
of broad interest, which excluded topics like “Reinforcement Learning” that we thought few
workers would know about. Second, we chose topics for which we could find existing online
quizzes in order to compare to human expert-generated assessments. Finally, we chose topics
that naturally lent themselves to textual questions and answers because Questimator does not
yet handle mathematical symbols, images, or video. With these criteria, we chose ten topics
across ten disciplines: customer satisfaction (marketing), earthquake (earth science), develop-
mental psychology (psychology), cell (biology), market structure (economics), Vietnam War
(history), metaphysics (philosophy), stroke (medicine), waste management (environmental sci-
ence), elasticity (physics). Quizzes were drawn from MOOCs (hosted by Coursera/edX), US
university/school board websites, and textbooks by major publishers (e.g., McGraw Hill). We
identified two expert-generated quizzes for two topics (Vietnam War and earthquake), and one
for each of the other topics (Table 4.1).

#### 4.1.2 Creating quizzes

To generate a quiz for a topic, we combined 10 questions from an expert quiz with the 10
Questimator questions. For each of the two topics for which we had two expert quizzes, we also
generated a quiz which consists of 20 expert questions only, as sampled from both quizzes.

---

Table 4.1: Expert Quiz Sources.

### 4.1.3 Selecting questions

Expert-generated quizzes varied in their length from 10 to 60 questions. To eliminate testing differences across topics, we randomly sampled 10 questions from each expert quiz, after removing questions that relied on numerical calculations and True-False questions wherever possible (if removing these questions resulted in fewer than 10 questions, we retained them). One of the two expert-generated quiz on the “Vietnam war” was drawn from a textbook chapter on the “Vietnam Era”, and questions on domestic issues like the Civil Rights Movement were removed before sampling. For each topic, we also generated 10 questions on Questimator.

### 4.1.4 Participants

Participants were recruited from Mechanical Turk. In all, 833 workers participated. All participants were paid $1 as base for their participation. To encourage participants to put in their best effort, we incentivized performance with a bonus payment of up to $4.

### 4.2 Experimental procedure

Participants were shown one question at a time (Figure 4.1). To reduce ordering effects [24], question order was randomized across participants. To reduce response-order biases [4], the order of answer choices was also randomized. Each question was also augmented with a textbox...
that asked participants to explain their reasoning (at least 15 characters), a technique that has been previously shown to encourage honest effort [20]. Finally, to discourage participants from using the Internet to search for answers, we monitored the web browser blur event and warned subjects that they would not be allowed to submit an answer if they left the window. Subjects spent an average of 58 seconds on each question. The average length of textbox comments was 66 characters, much longer than the required 15 characters. We received between 78 and 82 completed quizzes for each topic.

4.3 Objective 1: Correlation with Expert Quizzes

We computed a score for both the expert- and Questimator-generated questions for each participant. Each question was weighted equally. The median Pearson correlation between Questimator and expert quiz scores was 0.28 (Table 4.2). The highest correlation was 0.47 for “Customer satisfaction”, and the lowest was 0.08 for “Elasticity (physics)”. Of course, even expert-generated quizzes may not correlate highly: two experts may focus on different subtopics within a general topic, or prioritize different forms of knowledge. There-

Table 4.2: First column: Pearson correlations of quiz scores. Second and third columns: Mean of the questions’ $\alpha$s in a quiz.

fore, we also evaluated how well scores on two expert quizzes correlate for two topics. The Pearson correlation of the two scores for expert quizzes was 0.430 for “Earthquake” (vs 0.370 for the Questimator-expert) and 0.460 for “Vietnam War” (vs 0.275 for the Questimator-expert).

Figure ?? shows the scores and correlations between Questimator-expert and à expert-expert for “Earthquake”, to illustrate the variability and correlation between different groups of assessment questions.

Scores on Questimator quizzes correlate with expert quizzes to a lower but similar degree as to the two expert quizzes gathered for each category. We believe this means our quiz covers a subset of the whole topic space (also partially covered by expert quiz differently) using reasonable questions. Taken together, these results suggest that Questimator scores generally correlate quite well with expert quiz scores. And at least for one topic (Customer Satisfaction), this correlation value is as high as the correlation between two expert quizzes.

### 4.4 Objective 2: Question Discriminative Power

To analyze the discriminative power of questions, we used a very popular approach from psychometrics, Item Response Theory (IRT) [14] which is used to evaluate test items (questions) and analyze test takers. We fit a two-stage IRT model to analyze questions from a quiz under investigation (Questimator quiz) against a reference quiz (expert quiz) when they are mixed together for testing.

The IRT model we use is the unidimensional dichotomous model. For a student $i$ with ability $\theta_i \in \mathbb{R}$, the probability of success on the $j$th question item is

$$P(Y_j = 1|\theta_i) = \frac{1}{1 + e^{-\alpha_j \theta_i + \beta_j}},$$

(4.1)

where $\theta_i$ is the student ability, and $\alpha_j$ and $\beta_j$ are question parameters. $\theta_i$ is a scalar, implying single knowledge ability for the related term affects students’ performance on the quiz. $\alpha_j$ is the
question discriminative parameter, and $\beta_j$ is question difficulty. We selected this simple version of an IRT model to alleviate over-fitting. It can also be easily visualized and interpreted. For the IRT curve of an item (in our case, a question), $\alpha$ specifies the curve steepness (larger $\alpha$, steeper curve) and $\beta$ shifts the curve horizontally (larger $\beta$, more to the right). We want a steeper curve (in the extreme case, a step function), so there is less randomness in the score given a student’s ability. More specifically, we considered a Bayesian IRT model with a prior of

$$\theta_i \sim N(0, 1) \quad (4.2)$$

$$\alpha \sim N(\mu_\alpha = 1, \delta_\alpha^2) \quad (4.3)$$

$$\beta \sim N(\mu_\beta = 0, \delta_\beta^2) \quad (4.4)$$

$\mu_\alpha$ is set to be larger than 0 as we would suppose the questions have some positive discrimination effect. $\mu_\alpha$, $\mu_\beta$, $\delta_\alpha$ and $\delta_\beta$ can be set to reflect prior knowledge of the question items. We use MCMC to perform Bayesian inference and estimate the parameters of the model.  

### 4.4.1 Two stage IRT model fitting

We have two sets of questions (from experts and from Questimator) and if we estimated the IRT parameters independently, it would be less clear how to compare them. Instead, we fit two IRT models for each topic (i.e., each quiz mixture). We first fit one IRT model with the expert questions. We then treat the estimated student’s ability $\hat{\theta}_{i, \text{exp}}$ as the true underlying student abilities of the tested topic. We fix $\theta_i = \hat{\theta}_{i, \text{exp}}$ and fit another IRT model with Questimator questions, estimating only $\alpha$ and $\beta$ for the Questimator questions (Figure 4.2).

For “Customer satisfaction” (Pearson correlation across overall expert-Questimator question sets: 0.465), all of the questions have positive discrimination ($\alpha > 0$), and a fair amount have
relatively large $\alpha$s (steep sigmoid curve). On the other hand, for “Elasticity (physics)” (correlation: 0.083), the questions have lower discriminative power (smaller $\alpha$s). Indeed, a few have negative discrimination coefficients ($\alpha < 0$), meaning the more knowledgeable a student is on Elasticity, the less likely the student is to get the questions correct. With this method, we have a reliable evaluation of the quality of each question. Further investigation will help us to improve the weak aspects of the system, and to automatically eliminate problematic questions.

Table 4.2 shows the average $\alpha$ parameters values across the questions for each topic, both for the existing online quizzes and our Questimator-generated quizzes. These results suggest that for many topics Questimator is identifying questions that have positive discriminative power. In the future, it would be interesting to use this approach to automatically refine generated questions or question generation techniques.
Chapter 5

Discussion

5.1 Limitations in the current Questimator system

We manually inspected multiple-choice quizzes on more than a hundred topics, and found three common error-modes.

Because Questimator uses the target article’s text as the starting point for generating questions, we find its ability to generate good questions depends critically on the quality of the article text itself. First, when when the target article was too short (e.g., a Wikipedia “stub”), Questimator was unable to find enough related terms to generate a coherent quiz. Second, the current implementation of Questimator does not handle co-references well. For example, an article about “Ocean gyre” (a large system of circular ocean currents) may shorten it to “gyre” in most of the article, preventing Questimator from finding sentences about “ocean gyres.”

Questimator also fails when it can’t find enough information to distinguish the topic from related topics. For example, the exact phrase “an American singer, songwriter and actress” is used in Wikipedia to describe many artists, like Miley Cyrus, Katy Perry and Taylor Swift, leading to questions that test arcane knowledge (e.g., Figure 5.1, which asks if Miley Cyrus is also a record producer and choreographer).

Finally, Questimator does not reason about the real world. For example, it does not understand that “Syria Civil War” cannot be a military conflict in Lebanon (being a civil war).

5.2 Test taking strategies

Recall that in addition to marking the right answers, participants were also to provide a text explanation of their reasoning. While most responses were not informative (“It just sounds right to me.”), we found some participants guessed based on their knowledge of related topics. For example, given a question on President Nixon’s action in the Vietnam War, one participant remarked, “while I wasn’t alive when he was president, Nixon doesn’t strike me as a peaceful guy, so those answers were out.” Similarly, other participants used their general knowledge of the business world to answer the Customer Satisfaction quiz: “Customer centricity is the main factor to determine the [success of] business.” It is likely that Questimator questions are especially susceptible to such test-taking strategies as they use knowledge of related topics to generate questions.
the end of the quiz, workers are asked to provide optional feedback: “Is anything wrong with the questions? How can we improve the question quality? How can we improve this HIT?” The main types of the feedback are: (1) explanation why he/she might did well or bad, (2) enjoying it, (3) finding this difficult, (4) questions are all good, (5) spotting errors in one question and (6) discussion of the tested topic.

5.3 Promising approaches that were not effective

Because Wikipedia has a consistent editorial style (especially for popular or featured articles), simple approaches to selecting sentence stems work surprisingly well. In particular, Questimator processes sentences in order, as the first few sentences often explain the main topic. We also tried more complicated approaches, like LexRank [13], a popular document summarization method, but found it gave worse results.

To cover the main concepts of a topic comprehensively, related topics should ideally be maximally diverse. However, when we tried to use clustering techniques, like \( k \)-means and DBSCAN, results were disappointing. Possibly due to the relative link sparsity, we found these approaches usually resulted in one big cluster with majority of the candidate topics, and other clusters which contained single topics. Given these limitations, the current implementation of Questimator does not optimize the diversity of related topics.
5.4 What are Questimator quizzes suited for?

The goal of Questimator is to generate formative, fact-recall assessments for a broad range of topics. Our empirical evaluation found that Questimator-scores correlate significantly with scores on existing quizzes on a broad variety of topics, suggesting utility as formative assessment. For a self-directed learner, early, even approximate feedback about their gaps in understanding is useful in guiding future learning [29].

As such, Questimator quizzes are not designed as a replacement for expert-generated quizzes. Still, our empirical evaluation of Questimator shows that for many question types, Questimator scores correlate well with existing quizzes, and for some topics, score-correlations with an expert quiz and may be as high as correlations between two expert quizzes themselves. This suggests that approaches similar to Questimator may also help summative assessments, which can be used for applications such as certification. Assessments that go beyond fact-recall, and test deductive thinking, as well as questions that elicit an open-ended response may be necessary.
Chapter 6

Conclusion and Future Work

This paper has introduced Questimator, a system for generating formative, fact-recall questions on arbitrary topics. Our results show that our automatically generated questions are comparable to existing online quizzes on a variety of topics, and that we can generate quizzes for many topics for which no quiz currently exists. Future work will explore (i) improving the quality and the breadth of automatically created assessments, (ii) integrating it into systems for learning through testing, and (iii) utilizing additional corpora.

6.1 A broader variety of questions

Questimator assesses fact-recall through multiple-choice questions. Could we generate other kinds of assessments? For example, could a similar network-based model be used to allow students to complete a sentence fragment by filling in a blank without choices? Furthermore, Questimator currently only asks questions of identity (“X is Y”). Future work could also examine questions of entailment (“X means Y”) or causality (“X causes Y”), which are more important in different disciplines.

6.2 Using crowds to improve question quality

Could crowds continually improve the quality of questions Questimator generates? Using an active learning framework (and the IRT analysis described earlier), future work could preserve the breadth of Questimator for infrequently accessed topics, and approach the quality of expert-generated quizzes for topics that are more popular.

6.3 Learning through testing

Testing students on knowledge they are about to gain (pre-testing) can enhance learning [31, 32]. With Questimator, independent learners learning arbitrary topics can easily access MCQ quizzes for those topics. In future work, these questions could be integrated into personalized learning systems to leverage the testing effect. For example, a “learning interface” to Wikipedia
could show readers questions before they read an article. Furthermore, such fact-recall tests could personalize the content of knowledge sources themselves. Continuing with our imagined Wikipedia interface, future work could expand or summarize parts of articles based on what readers already know. We can assess the background knowledge of different aspects of the topic based on the testing results, and tailor the content we show to the learners.
